

# High-Efficiency, Main Power Supply Controllers for Notebook Computers

## General Description

The RT8205A/B/C dual step-down, switch-mode power-supply controller generates logic-supply voltages in battery-powered systems. The RT8205A/B/C includes two pulse-width modulation (PWM) controllers fixed at 5V/3.3V or adjustable from 2V to 5.5V. An alternative LGATE1 output LG1\_CP can be used for external charge pump (RT8205B). And an optional external charge pump can be monitored through SECFB (RT8205C). This device also features 2 linear regulators providing fixed 5V and 3.3V outputs. The linear regulator each provides up to 70mA output current with automatic linear-regulator bootstrapping to the PWM outputs. The RT8205A/B/C includes on-board power-up sequencing, the power-good output, internal soft-start, and internal soft-discharge output that prevents negative voltages on shutdown.

A constant on-time PWM control scheme operates without sense resistor and provides 100ns response to load transients while maintaining a relatively constant switching frequency. The unique ultrasonic mode maintains the switching frequency above 25kHz, which eliminates noise in audio applications. Other features include diode-emulation mode (DEM), which maximizes efficiency in light-load applications, and fixed-frequency PWM mode, which reduces RF interference in sensitive application

## Ordering Information

Note :

Richtek Green products are :

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

## Features

- Wide Input Voltage Range 6V to 25V
- Dual Fixed 5V/3.3V Outputs or Adjustable from 2V to 5.5V, 1.5% Accuracy.
- Alternative LGATE1 Output (LG1\_CP) acts as Clock for Charge Pump (RT8205B)
- Secondary Feedback Input Maintains Charge Pump Voltage (RT8205C).
- Fixed 3.3V and 5V LDO Output : 70mA
- 2V Reference Voltage  $\pm 1\%$  : 50uA
- Constant ON-Time Control with 100ns Load Step Response
- Frequency Selectable via TONSEL Setting
- $R_{DS(ON)}$  Current Sensing and Programmable Current Limit combined with Enable Control
- Selectable PWM, DEM, or Ultrasonic Mode
- Internal Soft-Start and Soft-Discharge
- High Efficiency up to 97%
- 5mW Quiescent Power Dissipation
- Thermal Shutdown
- RoHS Compliant and Halogen Free

## Applications

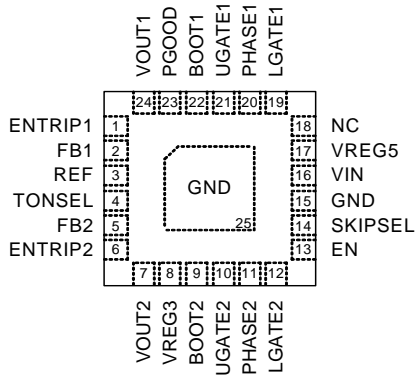

- Notebook and Sub-Notebook Computers
- 3-Cell and 4-Cell Li+ Battery-Powered Devices

## Marking Information

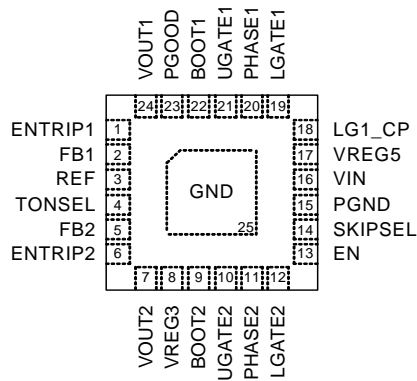

For marking information, contact our sales representative directly or through a Richtek distributor located in your area, otherwise visit our website for detail.

For Adjustable Voltage Regulator

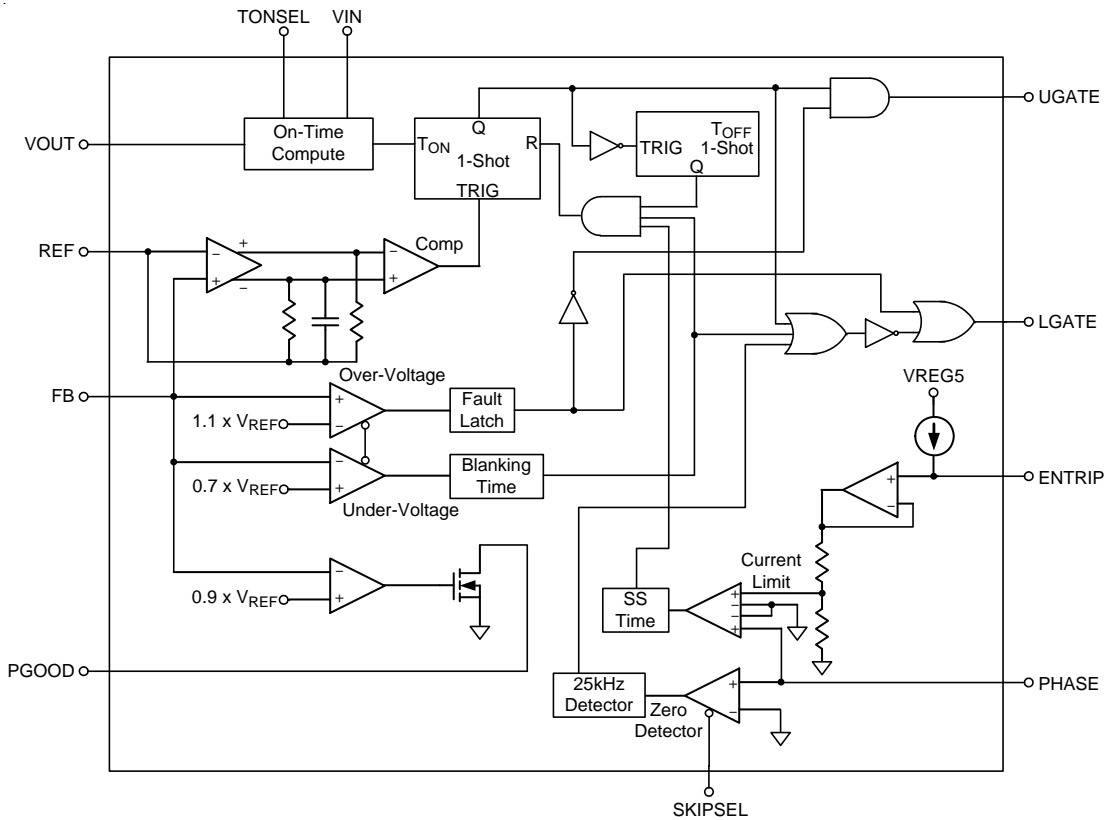

Function Block Diagram

Function Block Diagram

PWM Controller (One Side)

## Functional Pin Description

### ENTRIP1 (Pin 1)

Channel 1 enable and Current Limit setting Input. Connect resistor to GND to set the threshold for channel 1 synchronous  $R_{DS(ON)}$  sense. The GND-PHASE1 current-limit threshold is 1/10th the voltage seen at ENTRIP1 over a 0.5V to 2V range. There is an internal 10uA current source from VREG5 to ENTRIP1. The logic current limit threshold is default to 200mV value if ENTRIP1 is higher than VREG5-1V.

### FB1 (Pin 2)

SMPS1 Feedback Input. Connect FB1 to VREG5 or GND for fixed 5V operation. Or connect FB1 to a resistive voltage-divider from VOUT1 to GND to adjust output from 2V to 5.5V.

### REF (Pin 3)

2V Reference Output. Bypass to GND with a 0.22uF capacitor. REF can source up to 50uA for external loads. Loading REF degrades FBx and output accuracy according to the REF load-regulation error.

### TONSEL (Pin 4)

Frequency Selectable Input for VOUT1/VOUT2 respectively.

400kHz/500kHz : Connect to VREG5 or VREG3

300kHz/375kHz : Connect to REF

200kHz/250kHz : Connect to GND

### FB2 (Pin 5)

SMPS2 Feedback Input. Connect FB2 to VREG5 or GND for fixed 3.3V operation. Or connect FB2 to a resistive voltage-divider from VOUT2 to GND to adjust output from 2V to 5.5V.

### ENTRIP2 (Pin 6)

Channel 2 enable and Current Limit setting Input. Connect resistor to GND to set the threshold for channel 2 synchronous  $R_{DS(ON)}$  sense. The GND-PHASE2 current-limit threshold is 1/10th the voltage seen at ENTRIP2 over a 0.5V to 2V range. There is an internal 10uA current source

from VREG5 to ENTRIP2. The logic current limit threshold is default to 200mV value if ENTRIP2 is higher than VREG5-1V.

### VOUT2 (Pin 7)

SMPS2 Output Voltage-Sense Input. Connect to the SMPS2 output. VOUT2 is an input to the on-time one-shot circuit. It also serves as the SMPS2 feedback input in fixed-voltage mode.

### VREG3 (Pin 8)

3.3V Linear Regulator Output.

### BOOT2 (Pin 9)

Boost Flying Capacitor Connection for SMPS2. Connect to an external capacitor according to the typical application circuits.

### UGATE2 (Pin 10)

High-Side MOSFET Floating Gate-Driver Output for SMPS2. UGATE2 swings between PHASE2 and BOOT2.

### PHASE2 (Pin 11)

Inductor Connection for SMPS2. PHASE2 is the internal lower supply rail for the UGATE2 high-side gate driver. PHASE2 is also the current-sense input for the SMPS2.

### LGATE2 (Pin 12)

SMPS2 Synchronous-Rectifier Gate-Drive Output. LGATE2 swings between GND and VREG5.

### EN (Pin 13)

Master Enable Input. The REF/VREG5/VREG3 are enabled if it is within logic high level and disable if it is less than the logic low level.

### SKIPSEL (Pin 14)

Operation Mode Selectable Input.

Ultrasonic Mode : Connect to VREG5 or VREG3

Diode Emulation Mode : Connect to REF

PWM Mode : Connect to GND

**GND [Pin 15 (RT8205A), Exposed Pad (25)]**

Analog Ground for SMPS controller. The exposed pad must be soldered to a large PCB and connected to GND for maximum power dissipation.

**PGND (Pin 15) (RT8205B/C)**

Power Ground for SMPS controller. Connect PGND externally to the underside of the exposed pad.

**VIN (Pin 16)**

High Voltage Power Supply Input for 5V/3.3V LDO and Feed-forward ON-Time circuitry.

**VREG5 (Pin 17)**

5V Linear Regulator Output. VREG5 is also the supply voltage for the low-side MOSFET driver and analog supply voltage for the device.

**NC (Pin 18) (RT8205A)**

No Internal Connection.

**LG1\_CP (Pin 18) (RT8205B)**

Alternative LGATE1 Output for 14V charge pump.

**SECFB (Pin 18) (RT8205C)**

The SECFB is used to monitor the optional external 14V charge pump. Connect a resistive voltage-divider from 14V charge pump output to GND to detect the output. If SECFB drops below the threshold voltage, LGATE1 turns on for 300ns (typ.). This will refresh the external charge pump driven by LGATE1 without over-discharging the output voltage.

**LGATE1 (Pin 19)**

SMPS1 Synchronous-Rectifier Gate-Drive Output. LGATE1 swings between GND and VREG5.

**PHASE1 (Pin 20)**

Inductor Connection for SMPS1. PHASE1 is the internal lower supply rail for the UGATE1 high-side gate driver. PHASE1 is also the current-sense input for the SMPS1.

**UGATE1 (Pin 21)**

High-Side MOSFET Floating Gate-Driver Output for SMPS1. UGATE1 swings between PHASE1 and BOOT1.

**BOOT1 (Pin 22)**

Boost Flying Capacitor Connection for SMPS1. Connect to an external capacitor according to the typical application circuits.

**PGOOD (Pin 23)**

Power Good Output for channel 1 and channel 2. (Logical AND)

**VOUT1 (Pin 24)**

SMPS1 Output Voltage-Sense Input. Connect to the SMPS1 output. VOUT1 is an input to the on-time one-shot circuit. It also serves as the SMPS1 feedback input in fixed-voltage mode.

**Absolute Maximum Ratings** (Note 1)

• VIN, EN to GND	-----	-0.3V to 28V
• BOOTx to GND	-----	-0.3V to 34V
• PHASEx to GND		
DC	-----	-0.3V to 28V
< 20ns	-----	-8V
• BOOTx to PHASEx	-----	-0.3V to 6V
• ENTRIPx, SKIPSEL, TONSEL, PGOOD, to GND	-----	-0.3V to 6V
• VREG5, VREG3, FBx, VOUTx, SECFB, REF to GND	-----	-0.3V to (VREG5 + 0.3V)
• UGATEx to PHASEx		
DC	-----	-0.3V to (VREG5 + 0.3V)
< 20ns	-----	-5V
• LGATEx to GND		
DC	-----	-0.3V to (VREG5 + 0.3V)
< 20ns	-----	-2.5V
• Power Dissipation, P <sub>D</sub> @ T <sub>A</sub> = 25°C		
WQFN-24L 4x4	-----	1.923W
• Package Thermal Resistance (Note 4)		
WQFN-24L 4x4, θ <sub>JA</sub>	-----	52°C/W
WQFN-24L 4x4, θ <sub>JC</sub>	-----	7°C/W
• Lead Temperature (Soldering, 10 sec.)	-----	260°C
• Junction Temperature	-----	150°C
• Storage Temperature Range	-----	-65°C to 150°C
• ESD Susceptibility (Note 2)		
HBM (Human Body Mode)	-----	2kV
MM (Machine Mode)	-----	200V

**Recommended Operating Conditions** (Note 3)

• Input Voltage, V <sub>IN</sub>	-----	6V to 25V
• Junction Temperature Range	-----	-40°C to 125°C
• Ambient Temperature Range	-----	-40°C to 85°C

**Note 1.** Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Note 2.** Devices are ESD sensitive. Handling precaution is recommended.

**Note 3.** The device is not guaranteed to function outside its operating conditions.

**Note 4.**  $\theta_{JA}$  is measured in the natural convection at  $T_A = 25^\circ\text{C}$  on a high effective four layers thermal conductivity test board of JEDEC 51-7 thermal measurement standard. The case point of  $\theta_{JC}$  is on the expose pad for the WQFN package.

**Note 5.**  $P_{VIN} + P_{VREG5}$

**Application Information**

The RT8205A/B/C is a dual, Mach Response™ DRV™ dual ramp valley mode synchronous buck controller. The controller is designed for low-voltage power supplies for notebook computers. Richtek's Mach Response™ technology is specifically designed for providing 100ns “instant-on” response to load steps while maintaining a relatively constant operating frequency and inductor operating point over a wide range of input voltages. The topology circumvents the poor load-transient timing problems of fixed-frequency current-mode PWMs while avoiding the problems caused by widely varying switching frequencies in conventional constant-on-time and constant-off-time PWM schemes. The DRV™ mode PWM modulator is specifically designed to have better noise immunity for such a dual output application. The RT8205A/B/C includes 5V (VREG5) and 3.3V (VREG3) linear regulators. VREG5 linear regulator can step down the battery voltage to supply both internal circuitry and gate drivers. The synchronous-switch gate drivers are directly powered from VREG5. When VOUT1 voltage is above 4.66V, an automatic circuit will switch the power of the device from VREG5 linear regulator from VOUT1.

**PWM Operation**

The Mach Response™ DRV™ mode controller relies on the output filter capacitor's effective series resistance (ESR) to act as a current-sense resistor, so the output ripple voltage provides the PWM ramp signal. Refer to the RT8205A/B/C's function block diagram, the synchronous high-side MOSFET will be turned on at the beginning of each cycle. After the internal one-shot timer expires, the MOSFET will be turned off. The pulse width of this one shot is determined by the converter's input voltage and the output voltage to keep the frequency fairly constant over the input voltage range. Another one-shot sets a minimum off-time (300ns typ.). The on-time one-shot will be triggered if the error comparator is high, the low-side switch current is below the current-limit threshold, and the minimum off-time one-shot has timed out.

**PWM Frequency and On-Time Control**

The Mach Response™ control architecture runs with pseudo-constant frequency by feed-forwarding the input

and output voltage into the on-time one-shot timer. The high-side switch on-time is inversely proportional to the input voltage as measured by the  $V_{IN}$ , and proportional to the output voltage. There are two benefits of a constant switching frequency. The first is the frequency can be selected to avoid noise-sensitive regions such as the 455kHz IF band. The second is the inductor ripple-current operating point remains relatively constant, resulting in easy design methodology and predictable output voltage ripple. The frequency for 3V SMPS is set at 1.25 times higher than the frequency for 5V SMPS. This is done to prevent audio-frequency “beating” between the two sides, which switch asynchronously for each side. The frequencies are set by TONSEL pin connection as Table 1. The on-time is given by :

$$\text{On-Time} = K \times (V_{OUT} / V_{IN})$$

where “K” is set by the TONSEL pin connection (Table 1). The on-time guaranteed in the Electrical Characteristics tables are influenced by switching delays in the external high-side power MOSFET. Two external factors that influence switching-frequency accuracy are resistive drops in the two conduction loops (including inductor and PC board resistance) and the dead-time effect. These effects are the largest contributors to the change of frequency with changing load current. The dead-time effect increases the effective on-time, reducing the switching frequency as one or both dead times. It occurs only in PWM mode (SKIPSEL=GND) when the inductor current reverses at light or negative load currents. With reversed inductor current, the inductor's EMF causes PHASEx to go high earlier than normal, extending the on-time by a period equal to the low-to-high dead time. For loads above the critical conduction point, the actual switching frequency is :

$$f = (V_{OUT} + V_{DROPI}) / (t_{ON} \times (V_{IN} + V_{DROPI} - V_{DROPI2}))$$

where  $V_{DROPI}$  is the sum of the parasitic voltage drops in the inductor discharge path, including synchronous rectifier, inductor, and PC board resistances;  $V_{DROPI2}$  is the sum of the resistances in the charging path; and  $t_{ON}$  is the on-time calculated by the RT8205A/B/C.

**Table 1. TONSEL Connection and Switching Frequency**

TON	SMPS 1 K-Factor (us)	SMPS 1 Frequency (kHz)	SMPS 2 K-Factor (us)
GND	5	200	4
REF	3.33	300	2.67
VREG5 or VREG3	2.5	400	2

TON	SMPS 2 Frequency (kHz)	Approximate K-Factor Error (%)
GND	250	±10
REF	375	±10
VREG5 or VREG3	500	±10

### Operation Mode Selection (SKIPSEL)

The RT8205A/B/C supports three operation modes : Diode-Emulation Mode, Ultrasonic Mode, and Forced-CCM Mode.

#### Diode-Emulation Mode (SKIPSEL = REF)

In Diode-Emulation mode, The RT8205A/B/C automatically reduces switching frequency at light-load conditions to maintain high efficiency. This reduction of frequency is achieved smoothly and without increase of  $V_{OUT}$  ripple or load regulation. As the output current decreases from heavy-load condition, the inductor current is also reduced, and eventually comes to the point that its valley touches zero current, which is the boundary between continuous conduction and discontinuous conduction modes. By emulating the behavior of diodes, the low-side MOSFET allows only partial of negative current when the inductor free-wheeling current reach negative. As the load current is further decreased, it takes longer and longer to discharge the output capacitor to the level that requires the next "ON" cycle. The on-time is kept the same as that in the heavy-load condition. In reverse, when the output current increases from light load to heavy load, the switching frequency increases to the preset value as the inductor current reaches the continuous conduction. The transition load point to the light-load operation can be calculated as follows (Figure 1) :

$$I_{LOAD(SKIP)} \approx \frac{(V_{IN} - V_{OUT})}{2L} \times T_{ON}$$

where  $T_{on}$  is the On-time.

Figure 1. Boundary condition of CCM/DCM

The switching waveforms may appear noisy and asynchronous when light loading causes Diode-Emulation operation, but this is a normal operating condition that results in high light-load efficiency. Trade-offs in PFM noise vs. light-load efficiency are made by varying the inductor value. Generally, low inductor values produce a broader efficiency vs. load curve, while higher values result in higher full-load efficiency (assuming that the coil resistance remains fixed) and less output voltage ripple. Penalties for using higher inductor values include larger physical size and degraded load-transient response (especially at low input-voltage levels).

#### Ultrasonic Mode (SKIPSEL = VREG5 or VREG3)

Connecting SKIPSEL to VREG5 or VREG3 activates a unique Diode-Emulation mode with a minimum switching frequency of 25kHz. This ultrasonic mode eliminates audio-frequency modulation that would otherwise be present when a lightly loaded controller automatically skips pulses. In ultrasonic mode, the low-side switch gate-driver signal is OR with an internal oscillator (>25kHz). Once the internal oscillator is triggered, the ultrasonic controller pulls LGATE<sub>x</sub> high, turning on the low-side MOSFET to induce a negative inductor current. After the output voltage across the REF, the controller turns off the low-side MOSFET (LGATE<sub>x</sub> pulled low) and triggers a constant on-time (UGATE<sub>x</sub> driven high). When the on-time has expired, the controller re-enables the low-side MOSFET until the controller detects that the inductor current dropped below the zero-crossing threshold.

#### Forced-CCM Mode (SKIPSEL = GND)

The low-noise, forced-CCM mode (SKIPSEL = GND) disables the zero-crossing comparator, which controls the low-side switch on-time. This causes the low-side gate-driver waveform to become the complement of the high-

side gate-driver waveform. This in turn causes the inductor current to reverse at light loads as the PWM loop to maintain a duty ratio of  $V_{OUT}/V_{IN}$ . The benefit of forced-CCM mode is to keep the switching frequency fairly constant, but it comes at a cost : The no-load battery current can be 10mA to 40mA, depending on the external MOSFETs.

**Reference and linear Regulators (REF, VREGx)**

The 2V reference (REF) is accurate within  $\pm 1\%$  over temperature, making REF useful as a precision system reference. Bypass REF to GND with a 0.22uF (min) capacitor. REF can supply up to 50uA for external loads. Loading REF reduces the  $V_{OUTx}$  output voltage slightly because of the reference load-regulation error.

VREG5 regulator supplies total of 70mA for internal and external loads, including MOSFET gate driver and PWM controller. VREG3 regulator supplies up to 70mA for external loads. Bypass VREG5 and VREG3 with a 4.7uF (min) capacitor; use an additional 1uF per 5mA of internal and external load.

When the 5V main output voltage is above the VREG5 switchover threshold, an internal  $1.5\Omega$  N-Channel MOSFET switch connects  $V_{OUT1}$  to VREG5 while simultaneously shutting down the VREG5 linear regulator. Similarly, when the 3.3V main output voltage is above the VREG3 switchover threshold, an internal  $1.5\Omega$  N-Channel MOSFET switch connects  $V_{OUT2}$  to VREG3 while simultaneously shutting down the VREG3 linear regulator. It can decrease the power dissipation from the same battery, because the converted efficiency of SMPS is better than the converted efficiency of linear regulator.

**Current-Limit Setting (ENTRIPx)**

The RT8205A/B/C has cycle-by-cycle current limiting control. The current-limit circuit employs a unique “valley” current sensing algorithm. If the magnitude of the current-sense signal at PHASEx is above the current-limit threshold, the PWM is not allowed to initiate a new cycle (Figure 2). The actual peak current is greater than the current-limit threshold by an amount equal to the inductor ripple current. Therefore, the exact current-limit characteristic and maximum load capability are a function of the sense resistance, inductor value, and battery and output voltage.

Figure 2. “valley” Current-Limit

The RT8205A/B/C uses the on-resistance of the synchronous rectifier as the current-sense element. Use the worst-case maximum value for  $R_{DS(ON)}$  from the MOSFET datasheet, and add a margin of 0.5%/°C for the rise in  $R_{DS(ON)}$  with temperature.

The  $R_{ILIM}$  resistor between the ENTRIPx pin and GND sets the over current threshold. The resistor  $R_{ILIM}$  is connected to a 10uA current source from ENTRIPx. When the voltage drop across the sense resistor or low-side MOSFET equals 1/10 the voltage across the  $R_{ILIM}$  resistor, positive current limit will be activated. The high-side MOSFET will not be turned on until the voltage drop across the MOSFET falls below 1/10 the voltage across the  $R_{ILIM}$  resistor.

Choose a current limit resistor by following equation :

$$V_{ILIM} = (R_{ILIM} \times 10\mu A) / 10 = I_{ILIM} \times R_{DS(ON)}$$

$$R_{ILIM} = (I_{ILIM} \times R_{DS(ON)}) \times 10 / 10\mu A$$

Carefully observe the PC board layout guidelines to ensure that noise and DC errors do not corrupt the current-sense signal at PHASEx and GND. Mount or place the IC close to the low-side MOSFET.

**Charge Pump (LG1\_CP or SECFB)**

The external 14V charge pump is driven by LGATE1 (Figure 3 and Figure 4). When LGATE1 is low, the C1 will be charged by D1 from  $V_{OUT1}$ . C1 voltage is equal to  $V_{OUT1}$  minus a diode drop. When LGATE1 transitions to high, the charges from C1 will transfer to C2 through D2 and charge it to  $V_{LGATE1}$  plus  $V_{C1}$ . As LGATE1 transitions low on the next cycle, C2 will charge C3 to its voltage minus a diode drop through D3. Finally, C3 charges C4 through D4 when LGATE1 switched to high. So,  $V_{CP}$  voltage is :

$$V_{CP} = V_{OUT1} + 2 \times V_{LGATE1} - 4 \times V_D$$

Where  $V_{LGATE1}$  is the peak voltage of LGATE1 driver and is equal to the VREG5;  $V_D$  is the forward diode dropped across the Schottky.

LG1\_CP in the RT8205B (Figure 3) can be used as clock signal for charge pump circuit to generate approximately 14V DC voltage and the clock driver uses VOUT1 as its power supply, SECFB in the RT8205C is used to monitor the charge pump through resistive divider (Figure 4). In an event when SECFB dropped below 2V, the detection circuit forces the high-side MOSFET off and the low-side MOSFET on for 300ns to allow CP to recharge and SECFB rise above 2V. In the event of an overload on CP where SECFB can not reach more than 2V, the monitor will be cancelled. Special care should be taken to ensure enough normal voltage ripple on each cycle as to prevent CP shut-down.

The SECFB pin has ~17mV of hysteresis, so the ripple should be enough to bring the SECFB voltage above the threshold by ~3x the hysteresis, or  $(2V + 3 \times 17mV) = 2.051V$ . Reducing the CP decoupling capacitor and placing a small ceramic capacitor (10 pF to 47pF) ( $C_F$  of Figure 4) in parallel with the upper leg of the SECFB resistor network ( $R_{CP1}$  of Figure 4) will also increase the robustness of the charge pump.

Figure 3. Connect to LG1\_CP

Figure 4. Connect to SECFB

### MOSFET Gate Driver (UGATE<sub>x</sub>, LGATE<sub>x</sub>)

The high-side driver is designed to drive high-current, low  $R_{DS(ON)}$  N-Channel MOSFET(s). When configured as a floating driver, 5-V bias voltage is delivered from VREG5 supply. The average drive current is also calculated by the gate charge at  $V_{GS} = 5V$  times switching frequency.

The instantaneous drive current is supplied by the flying capacitor between BOOT<sub>x</sub> and PHASE<sub>x</sub> pins. A dead time to prevent shoot through is internally generated between high-side MOSFET off to low-side MOSFET on, and low-side MOSFET off to high-side MOSFET on.

The low-side driver is designed to drive high current low  $R_{DS(ON)}$  N-Channel MOSFET(s). The internal pull-down transistor that drives LGATE<sub>x</sub> low is robust, with a 0.6Ω typical on-resistance. A 5V bias voltage is delivered from VREG5 supply. The instantaneous drive current is supplied by an input capacitor connected between VREG5 and GND.

For high-current applications, some combinations of high- and low-side MOSFETs might be encountered that will cause excessive gate-drain coupling, which can lead to efficiency-killing, EMI-producing shoot-through currents. This is often remedied by adding a resistor in series with BOOT<sub>x</sub>, which increases the turn-on time of the high-side MOSFET without degrading the turn-off time (Figure 5).

Figure 5. Reducing the UGATE<sub>x</sub> Rise Time

### Soft-Start

A build-in soft-start is used to prevent surge current from power supply input after ENTRIP<sub>x</sub> is enabled. The typical soft-start duration is 2ms period. Furthermore, the maximum allowed current limit is segmented in 5 steps: 20%, 40%, 60%, 80% and 100% during the 2ms period.

### UVLO Protection

The RT8205A/B/C has VREG5 under voltage lock out protection (UVLO). When the VREG5 voltage is lower than 4.2V (typ.) and the VREG3 voltage is lower than 2.5V (typ.), both switch power supplies are also shut off. This is non-latch protection.

**Power-Good Output (PGOOD)**

The PGOOD is an open-drain type output and requires a pull-up resistor. PGOOD is actively held low in soft-start, standby, and shutdown. It is released when both outputs voltage above than 92.5% of nominal regulation point. The PGOOD goes low if either output turns off or is 10% below its nominal regulator point.

**Output Over Voltage Protection (OVP)**

The output voltage can be continuously monitored for over voltage. When over voltage protection is enabled, if the output voltage exceeded 11% of its set voltage threshold, the over voltage protection is triggered and the LGATE<sub>x</sub> low-side gate drivers are forced high. This activates the low-side MOSFET switch, which rapidly discharges the output capacitor and pulls the input voltage downward.

RT8205A/B/C is latched once OVP is triggered and can only be released by EN power-on reset. There is 10us delay built into the over voltage protection circuit to prevent false transition.

Note that LGATE<sub>x</sub> latching high causes the output voltage to dip slightly negative when energy has been previously stored in the LC tank circuit. For loads that cannot tolerate a negative voltage, place a power Schottky diode across the output to act as a reverse polarity clamp.

If the over voltage condition is caused by a short in high-side switch, turning the low-side MOSFET on 100% creates an electrical short between the battery and GND, blowing the fuse and disconnecting the battery from the output.

**Output Under voltage Protection (UVP)**

The output voltage can be continuously monitored for under voltage. When under voltage protection is enabled, if the output is less than 70% of its set voltage threshold, under voltage protection is triggered, then both UGATE<sub>x</sub> and LGATE<sub>x</sub> gate drivers are forced low while entering soft-discharge mode. During soft-start, the UVP will be blanked around 3ms.

**Thermal Protection**

The RT8205A/B/C have thermal shutdown to prevent the overheat damage. Thermal shutdown occurs when the die temperature exceeds +150°C. All internal circuitry shuts down during thermal shutdown. The RT8205A/B/C triggers

thermal shutdown if VREG<sub>x</sub> is not supplied from VOUT<sub>x</sub>, while input voltage on VIN and drawing current from VREG<sub>x</sub> are too high. Even if VREG<sub>x</sub> is supplied from VOUT<sub>x</sub>, overloading the VREG<sub>x</sub> causes large power dissipation on automatic switches, which may result in thermal shutdown.

**Discharge Mode (Soft-Discharge)**

When ENTRIP<sub>x</sub> is low and a transition to standby or shutdown mode occurs, or the output under voltage fault latch is set, the outputs discharge mode will be triggered. During discharge mode, there is one path to discharge the outputs capacitor residual charge. That is output capacitor discharge to GND through an internal switch.

**Shutdown Mode**

The RT8205A/B/C SMPS1, SMPS2, VREG3 and VREG5 have independent enabling control. Drive EN, ENTRIP1 and ENTRIP2 below the precise input falling-edge trip level to place the RT8205A/B/C in its low-power shutdown state. The RT8205A/B/C consumes only 20uA of input current while in shutdown.

**Power-Up Sequencing and On/Off Controls (ENTRIP<sub>x</sub>)**

ENTRIP1 and ENTRIP2 control SMPS power-up sequencing. When the RT8205A/B/C applies in the single channel mode, ENTRIP1 or ENTRIP2 enables the respective outputs when ENTRIP<sub>x</sub> voltage rising above 0.4V.

If both of ENTRIP1 and ENTRIP2 become higher than the enable threshold voltage at a different time (without 60us), one can force the latter one output starts after the former one regulates.

**Output Voltage Setting (FB<sub>x</sub>)**

Connect FB<sub>x</sub> directly to GND or VREG5 to enable the fixed, SMPS output voltages (3.3V and 5V). Connect a resistor voltage-divider at the FB<sub>x</sub> between the VOUT<sub>x</sub> and GND to adjust the respective output voltage between 2V and 5.5V (Figure 6). Choose R2 to be approximately 10kΩ, and solve for R1 using the equation :

$$V_{OUTx} = V_{FBx} \times \left[ 1 + \left( \frac{R1}{R2} \right) \right]$$

where V<sub>FB<sub>x</sub></sub> is 2V (typ.).

VREG5 connects to VOUT1 through an internal switch only when VOUT1 is above the VREG5 automatic switch threshold (4.66V). VREG3 connects to VOUT2 through an internal switch only when VOUT2 is above the VREG3 automatic switch threshold (3.06V). This is the most effective way when the fixed output voltages are used. Once VREGx is supplied from VOUTx, the internal linear regulator turns off. This reduces internal power dissipation and improves efficiency when the VREGx is powered with a high input voltage.

Figure 6. Setting VOUTx with a Resistor-Divider

### Output Inductor Selection

The switching frequency (on-time) and operating point (% ripple or  $L_{IR}$ ) determine the inductor value as shown as follows :

$$L = \frac{T_{ON} \times (V_{IN} - V_{OUTx})}{L_{IR} \times I_{LOAD(MAX)}}$$

where  $L_{IR}$  is the ratio of the peak to peak ripple current to the average inductor current.

Find a low-loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. Ferrite cores are often the best choice, although powdered iron is inexpensive and can work well at 200kHz. The core must be large enough not to saturate at the peak inductor current ( $I_{PEAK}$ ):

$$I_{PEAK} = I_{LOAD(MAX)} + [(L_{IR} / 2) \times I_{LOAD(MAX)}]$$

This inductor ripple current also impacts transient-response performance, especially at low  $V_{IN} - V_{OUTx}$  differences. Low inductor values allow the inductor current to slew faster, replenishing charge removed from the output filter capacitors by a sudden load step. The peak amplitude of the output transient  $V_{SAG}$  is also a function of the output transient. The  $V_{SAG}$  also features a function of the

maximum duty factor, which can be calculated from the on-time and minimum off-time :

$$V_{SAG} = \frac{(\Delta I_{LOAD})^2 \times L \times \left( K \frac{V_{OUTx}}{V_{IN}} + T_{OFF(MIN)} \right)}{2 \times C_{OUT} \times V_{OUTx} \times \left[ K \left( \frac{V_{IN} - V_{OUTx}}{V_{IN}} \right) - T_{OFF(MIN)} \right]}$$

Where minimum off-time ( $T_{OFF(MIN)}$ ) = 300ns (typ.) and K is from Table 1.

### Output Capacitor Selection

The output filter capacitor must have low enough ESR to meet output ripple and load-transient requirements, yet have high enough ESR to satisfy stability requirements. Also, the capacitance value must be high enough to absorb the inductor energy going from a full-load to no-load condition without tripping the OVP circuit.

For CPU core voltage converters and other applications where the output is subject to violent load transients, the output capacitor's size depends on how much ESR is needed to prevent the output from dipping too low under a load transient. Ignoring the sag due to finite capacitance :

$$ESR \leq \frac{V_{P-P}}{I_{LOAD(MAX)}}$$

In non-CPU applications, the output capacitor's size depends on how much ESR is needed to maintain an acceptable level of output voltage ripple :

$$ESR \leq \frac{V_{P-P}}{L_{IR} \times I_{LOAD(MAX)}}$$

where  $V_{P-P}$  is the peak-to-peak output voltage ripple.

Organic semiconductor capacitor(s) or specialty polymer capacitor(s) are recommended.

For low input-to-output voltage differentials ( $V_{IN}/V_{OUTx} < 2$ ), additional output capacitance is required to maintain stability and good efficiency in ultrasonic mode.

The amount of overshoot due to stored inductor energy can be calculated as :

$$V_{SOAR} \leq \frac{(I_{PEAK})^2 \times L}{2 \times C_{OUT} \times V_{OUTx}}$$

where  $I_{PEAK}$  is the peak inductor current.

**Output Capacitor Stability**

Stability is determined by the value of the ESR zero relative to the switching frequency. The point of instability is given by the following equation :

$$f_{ESR} = \frac{1}{2 \times \pi \times ESR \times C_{OUT}} \leq \frac{f_{SW}}{4}$$

Do not put high-value ceramic capacitors directly across the outputs without taking precautions to ensure stability. Large ceramic capacitors can have a high- ESR zero frequency and cause erratic, unstable operation. However, it is easy to add enough series resistance by placing the capacitors a couple of inches downstream from the inductor and connecting VOUTx or the FBx divider close to the inductor.

Unstable operation manifests itself in two related and distinctly different ways: double-pulsing and feedback loop instability.

Double-pulsing occurs due to noise on the output or because the ESR is so low that there is not enough voltage ramp in the output voltage signal. This “fools” the error comparator into triggering a new cycle immediately after the 300ns minimum off-time period has expired. Double-pulsing is more annoying than harmful, resulting in nothing worse than increased output ripple. However, it may indicate the possible presence of loop instability, which is caused by insufficient ESR.

Loop instability can result in oscillations at the output after line or load perturbations that can trip the overvoltage protection latch or cause the output voltage to fall below the tolerance limit.

The easiest method for checking stability is to apply a very fast zero-to-max load transient and carefully observe the output-voltage-ripple envelope for overshoot and ringing. It helps to simultaneously monitor the inductor current with an AC current probe. Do not allow more than one cycle of ringing after the initial step-response under- or overshoot.

**Thermal Considerations**

For continuous operation, do not exceed absolute maximum operation junction temperature. The maximum power dissipation depends on the thermal resistance of IC package, PCB layout, the rate of surroundings airflow

and temperature difference between junction to ambient. The maximum power dissipation can be calculated by following formula :

$$P_{D(MAX)} = ( T_{J(MAX)} - T_A ) / \theta_{JA}$$

Where  $T_{J(MAX)}$  is the maximum operation junction temperature,  $T_A$  is the ambient temperature and the  $\theta_{JA}$  is the junction to ambient thermal resistance.

For recommended operating conditions specification of RT8205, the maximum junction temperature is 125°C. The junction to ambient thermal resistance  $\theta_{JA}$  is layout dependent. For WQFN-24L 4x4 packages, the thermal resistance  $\theta_{JA}$  is 52°C/W on the standard JEDEC 51-7 four layers thermal test board. The maximum power dissipation at  $T_A = 25^\circ\text{C}$  can be calculated by following formula :

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (52^\circ\text{C/W}) = 1.923\text{W for WQFN-24L 4x4 packages}$$

The maximum power dissipation depends on operating ambient temperature for fixed  $T_{J(MAX)}$  and thermal resistance  $\theta_{JA}$ . For RT8205 packages, the Figure 7 of derating curves allows the designer to see the effect of rising ambient temperature on the maximum power allowed.

Figure 7. Derating Curves for RT8205A/B/C Packages

## Layout Considerations

Layout is very important in high frequency switching converter design. If the IC is designed improperly, the PCB could radiate excessive noise and contribute to the converter instability. Certain points must be considered before starting a layout using the RT8205A/B/C.

- ▶ Place the filter capacitor close to the IC, within 12 mm (0.5 inch) if possible.
- ▶ Keep current limit setting network as close as possible to the IC. Routing of the network should avoid coupling to high-voltage switching node.
- ▶ Connections from the drivers to the respective gate of the high-side or the low-side MOSFET should be as short as possible to reduce stray inductance. Use 0.65-mm (25 mils) or wider trace.
- ▶ All sensitive analog traces and components such as VOUTx, FBx, GND, ENTRIPx, PGOOD, and TONSEL should be placed away from high-voltage switching nodes such as PHASEx, LGATEx, UGATEx, or BOOTx nodes to avoid coupling. Use internal layer(s) as ground plane(s) and shield the feedback trace from power traces and components.
- ▶ Gather ground terminal of VIN capacitor(s), VOUTx capacitor(s), and source of low-side MOSFETs as close as possible. PCB trace defined as PHASEx node, which connects to source of high-side MOSFET, drain of low-side MOSFET and high-voltage side of the inductor, should be as short and wide as possible.

**Table 2. Operation Mode Truth Table**

Mode	Condition	Comment
<b>Power-UP</b>	VREGx < UVLO threshold	Transitions to discharge mode after a VIN POR and after REF becomes valid. VREG5, VREG3, and REF remain active.
<b>RUN</b>	EN = high, VOUT1 or VOUT2 enabled	Normal Operation.
<b>Over Voltage Protection</b>	Either output > 111% of the nominal level.	LGATEx is forced high. VREG3, VREG5 active. Exited by VIN POR or by toggling EN, ENTRIPx
<b>Under Voltage Protection</b>	Either output < 70% of the nominal level after 3ms time-out expires and output is enabled	Both UGATEx and LGATEx are forced low and enter discharge mode. VREG3, VREG5 active. Exited by VIN POR or by toggling EN, ENTRIPx
<b>Discharge</b>	Either SMPS output is still high in either standby mode or shutdown mode	During discharge mode, there is one path to discharge the outputs capacitor residual charge. That is output capacitor discharge to GND through an internal switch.
<b>Standby</b>	ENTRIPx < startup threshold, EN = high.	VREG3, VREG5 active.
<b>Shutdown</b>	EN = low	All circuitry off.
<b>Thermal Shutdown</b>	TJ > +150°C	All circuitry off. Exit by VIN POR or by toggling EN, ENTRIPx.

**Table 3. Power-Up Sequencing**

EN (V)	ENTRIP1 (V)	ENTRIP2 (V)	VREG5	VREG3	SMPS1	SMPS2
Low	X	X	Off	Off	Off	Off
">1V" => High	Low	Low	On (after REF powers up)	On (after REF powers up)	Off	Off
">1V" => High	Low	High	On (after REF powers up)	On (after REF powers up)	Off	On
">1V" => High	High (after ENTRIP2 is high without 60us)	High	On (after REF powers up)	On (after REF powers up)	On (after SMPS2 on)	On
">1V" => High	High	Low	On (after REF powers up)	On (after REF powers up)	On	Off
">1V" => High	High	High (after ENTRIP1 is high without 60us)	On (after REF powers up)	On (after REF powers up)	ON	On (after SMPS1 on)
">1V" => High	High	High	On (after REF powers up)	On (after REF powers up)	On	On
